

China just recently shot down an old satellite. Satellites are very important navigational devices used by ships, military, and NASA. They use GPS' (global positioning satellites) that are needed to determine a destination; example, a space shuttle going to the moon, where would it be without directions? Right now these satellites are outdated technology. Also they allow people to communicate with one another. We should make a stealth, or undetected smaller satellite with a missile defense system. This would help because if foreign countries continue to shoot these satellites down, all NASA and military devices would be useless.
